Background: Pancreatic cancer (PC) is aggressive and with poor clinical prognosis. However, mechanisms underlying the aggressiveness of PC remain unclear. Increasing evidence indicates that cholesterol, a major source of bio-energy, is required for the progression of human cancers including PC. Therefore, this study aimed to investigate the anti-tumor effect of atorvastatin, a widely used lipid-lowering agent that blocks the production of cholesterol, on human PC.

Methods: We firstly assessed the impacts of atorvastatin on the proliferation, apoptosis, cell cycle distribution, migration and invasion of human PC cells PANC-1 and SW1990. Furthermore, we studied the effects of atorvastatin on neurotrophin receptor signaling, including nerve growth factor (NGF), brain-derived neurotrophic factor (BDNF), neurotrophin-3 (NT-3) and their downstream receptors tropomyosin receptor kinase (Trk) Trk A, Trk B and Trk C in human PC cells.

Results: Atorvastatin significantly inhibited the proliferation, migration and invasion, and induced G1-phase cell cycle arrest and apoptosis in both PANC-1 and SW1990 cells. Meanwhile, atorvastatin treatment remarkably suppressed the expression of NGF, BDNF, and NT-3 as well as that of their downstream receptors Trk A and Trk C.

Conclusions: These results provide evidence that atorvastatin inhibits the proliferation, migration and invasion ability of human PC cells, and atorvastatin may exert the anti-tumor effect in PC via the inhibition of neurotrophin signaling pathway.

Keywords: Pancreatic cancer (PC); atorvastatin; neurotrophin receptor

Introduction

Pancreatic cancer (PC) is a devastating disease with an extremely poor median survival of less than 6 months due to its aggressive nature. Each year, approximately 40,000 individuals are diagnosed with this lethal malignancy worldwide. It is now the 7th leading cause of cancer-

related death globally (1-3). At the time of diagnosis, only approximately 15% of patients are candidates for potentially curative surgery, the remainders are already in advanced stages with unresectable lesions (2,4). For patients with unresectable disease, chemotherapy and radiotherapy remain the standard treatment options. However, PC cells are typically resistant to most of these conventional therapeutic

modalities (5-7). Therefore, novel therapeutic strategies are in urgent need to reverse this dismal condition and improve prognosis associated with PC.

Recent evidence has suggested an essential role of cholesterol in the tumorigenesis and development of several human cancers including PC. In one meta-analysis, the authors analyzed 20 published articles encompassing 2,245,052 participants and concluded that dietary cholesterol may be associated with an increased risk for PC (8). Meanwhile, another study found that cholesterol uptake is aberrantly activated in PC cells and blocking cholesterol uptake not only inhibited proliferation but also increased the chemo-sensitivity of human PC cells (9). Furthermore, the prevention of cholesterol biosynthesis has been reported to sensitize PC cells to radiotherapy (10). Taken together, these data suggest that cholesterol is a promising target for clinical PC treatment.

Atorvastatin is a cholesterol-lowering agent that works by competitively inhibiting 3-hydroxy-3-methylglutarylcoenzyme-A (HMG CoA) reductase; it has been in clinical use for many years with an established safety profile (11). Several recent studies have found that statins exert antitumor activities in various common malignancies including breast, liver and colon cancer (12,13). Therefore, the aim of this present study is to investigate the effect and potential underlying mechanism of atorvastatin on the proliferation, apoptosis, cell cycle distribution, migration, invasion of human PC cell lines, providing rationale for atorvastatin as a novel targeted molecular agent for clinical PC therapy.

Methods

Cell culture and reagents

The human PC cell lines PANC-1 and SW1990 were purchased from Shanghai Cell Bank (Shanghai, China). Both cell types were cultured in Dulbecco's Modified Eagle Media (DMEM) medium supplemented with 10% fetal bovine serum, 1% penicillin and streptomycin, and grown in a humidified incubator at 37 °C with 5% CO₂. All tissue culture reagents and atorvastatin were purchased from Sigma-Aldrich (St. Louis, MO, USA).

Cell viability assay

Cell viability was determined by the CellTiter-Glo luminescent cell viability assay. Briefly, PANC-1 and SW1990 cells (2×10^3) were seeded onto 96-well culture

plates. After incubation overnight, the medium was replaced with fresh medium containing dimethyl sulfoxide (DMSO) (vehicle control) or different concentrations of atorvastatin. After incubation for the indicated time, 20 μ L of CellTiter 96® AQ_{ueous} One Solution Reagent (Promega, Madison, WI, USA) was added to each well. After incubation for another 2 h, the optical density (OD) was measured using an ELx800 plate reader (Bio-Tek; Winooski, VT, USA) at a wavelength of 490 nm. All samples were run in triplicate.

Colony formation assay

PANC-1 and SW1990 cells were trypsinized and plated (800 cells/well) onto 12-well tissue culture plates; the medium was replaced with fresh medium containing different concentrations of atorvastatin 24 h later. After 6 days of incubation, cells were rinsed with 1× PBS, fixed with methanol and stained with 0.1% crystal violet. The numbers of colonies were counted manually.

Apoptosis and cell cycle distribution analysis by flow cytometry

The apoptosis and cell cycle distribution of PANC-1 and SW1990 cells were determined by the Annexin V-FITC detection kit (Becton, Dickinson and Company, USA). Cells were inoculated onto 6-well tissue culture plates (3×10^4 cells/well) and treated with different concentrations of atorvastatin for the indicated times. The cells were then trypsinized, washed twice with ice-cold PBS and resuspended in 1× binding buffer at a concentration of 10^5 /mL in a total volume of 100 μ L. Subsequently, 5 μ L of both Annexin V-FITC and PI were added, and the samples were oscillated gently to evaluate the apoptosis rate and cell cycle distribution via flow cytometry. All samples were run in triplicate.

Wound healing assay

For the wound healing assay, 90% confluent monolayers of PANC-1 and SW1990 cells with or without atorvastatin treatment were "wounded" using a pipette tip. The wounds were photographed (0, 24 and 48 h) in the same area, and the wound healing rate was measured.

Migration and invasion assay

Briefly, PANC-1 or SW1990 (5×10^4) cells were seeded

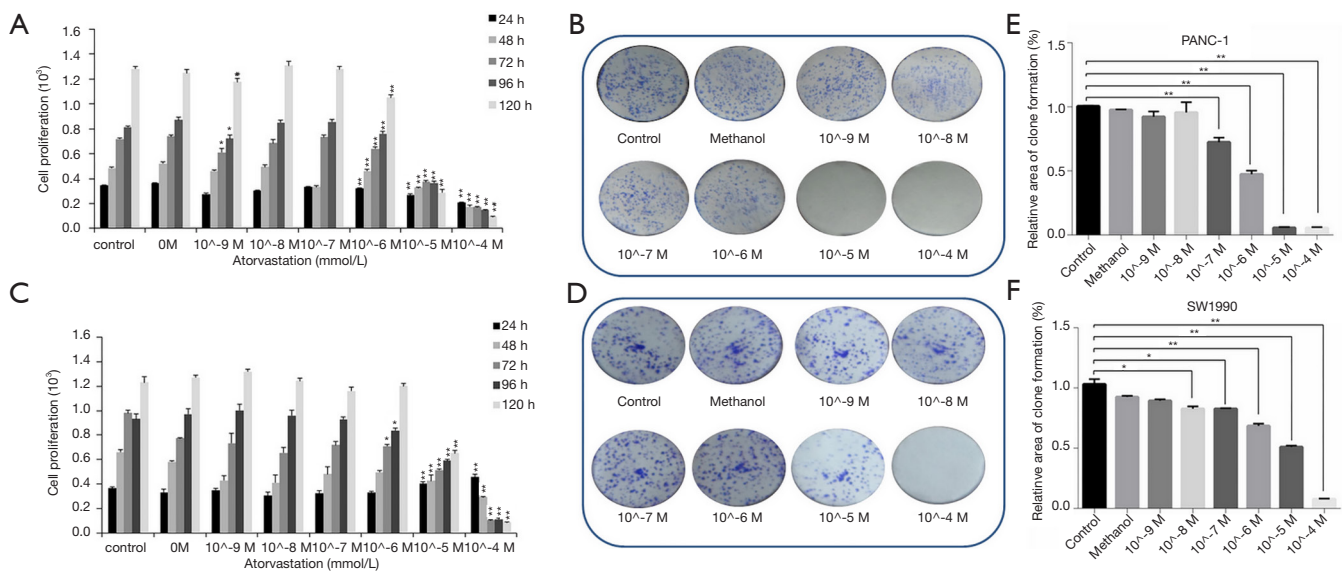

Figure 1 Atorvastatin inhibits proliferation in pancreatic cancer cells. PANC-1 and SW1990 cells were treated with different concentrations of atorvastatin for indicated times. Then, cell proliferation was detected by CellTiter-Glo luminescent cell viability assay (A,C) and colony formation assay (B,D). The relative numbers of colonies were calculated (E,F). Statistical significance was presented as *, $P \leq 0.05$; **, $P \leq 0.01$.

onto the upper chamber in fetal bovine serum (FBS)-free medium with different concentrations of atorvastatin, and medium with 10% FBS was added into each lower chamber of 24-well tissue culture plates; cells were allowed to migrate and invade through the membrane pores with or without Matrigel for 20 h. The cells on the surface of the lower side of the chamber were then fixed, stained (Calcein AM), and photographed. Five visual fields were photographed in every membrane, and the stained cells were manually counted. All samples were run in triplicate. For the invasion assay, crystal violet was dissolved in 70% acetic acid, and the absorbance of each well was measured by a microplate reader at a wavelength of 450 nm.

Western blotting

Cells were harvested and lysed in Radio-Immunoprecipitation Assay (RIPA) lysis buffer (Beyotime Biotechnology, China) containing protease inhibitors for 20 min at 4 °C. The proteins were separated by 10% dodecyl sulfate, sodium salt-Polyacrylamide gel electrophoresis (SDS-PAGE) and transferred to polyvinylidene fluoride (PVDF) membranes (Millipore, USA). After blocking with 5% milk, the samples were incubated with the primary antibodies. The membranes were then incubated with a horseradish peroxidase (HRP)-conjugated anti-rabbit or

anti-mouse secondary antibody (Jackson ImmunoResearch, USA). The protein bands were visualized using enhanced chemiluminescence (ECL, Beyotime Biotechnology, China). Endogenous β -actin protein expression was detected as the internal control for each sample.

The primary antibodies included β -actin (Beyotime Biotechnology, China), caspase-3 (Abcam, USA), p21 (Abcam, USA), p-chk2 (Abcam, USA), NGF/TrkA, BDNF/TrkB, NT3/TrkC and p75 (Abcam, USA).

Statistics

Results are expressed as the means \pm SEM and were analyzed using SPSS 22.0. Statistical comparisons between groups were performed using two-way ANOVA. $P < 0.05$ was considered statistically significant.

Results

Atorvastatin inhibits the proliferation of PC cells

To assess the impact of atorvastatin on the proliferation of human PC, PANC-1 and SW1990 cells were treated with different concentrations of atorvastatin for the indicated times. Then, the CellTiter-Glo luminescent cell viability assay was conducted. As shown in *Figure 1A* and *B*,

atorvastatin treatment inhibited the proliferation of PC cells in a dose-dependent manner. The colony formation assay was also conducted. As shown in *Figure 1C* and *D*, the atorvastatin treatment exerted anti-proliferation effect in PC cells. Particularly, the numbers of viable PANC-1 and SW1990 colonies were significantly decreased after atorvastatin (1 nM or higher) treatment, as shown in *Figure 1E* and *F*. These above results indicated that atorvastatin can inhibit the proliferation ability of PC cells *in vitro*.

Atorvastatin induces apoptosis in PC cells (Figures 2,3)

Next, we studied whether atorvastatin treatment can induce apoptosis in PC cells by flow cytometry. The results showed that 10 nM or higher dose of atorvastatin treatments efficiently induced apoptosis of both PANC-1 (*Figures 2A,3A*) and SW1990 cells (*Figures 2B,3B*).

Atorvastatin induces the G1-cell cycle arrest of PC cells

We further investigated whether atorvastatin-mediated anti-proliferation effect in PC cells was related to cell cycle arrest. As shown in *Figures 3A* and *4A*, 10 nM or higher dose of atorvastatin treatment significantly increased the percent of G1 phase in both PANC-1 and SW1990 cells. Correspondingly, the percentages of S and G2 phase cells were significantly decreased (*Figures 3B,C,4B,C*). Meanwhile, western blot analysis showed the increase of p21 expression (*Figure 5*) and decrease of phosphorylated checkpoint kinase 2 Thr68 (Chk2-T68) expression (*Figure 5*) after atorvastatin treatment in both PANC-1 and SW1990 cells. The above results demonstrate that atorvastatin induces G1 arrest in PC cells.

Atorvastatin inhibits the migration and invasion of PC cells

We further explored the impact of atorvastatin on the migration and invasion of PC cells. Wound healing assay results showed that 10 nM or higher dose of atorvastatin treatment significantly decreased the rate of wound closure in both cells compared to control group (*Figure 6*). Meanwhile, transwell invasion assay results demonstrated that atorvastatin treatment markedly reduced the invasion ability of both cells (*Figure 7*). These results above indicated that atorvastatin can inhibit the migration and invasion ability of PC cells.

Atorvastatin decreased the expression of neurotrophins and their receptors

Finally, the potential mechanism underlying the antitumor effect of atorvastatin on PC cells was assessed. Since the neurotrophin signaling pathway has been extensively implicated in the malignant behavior in various types of human malignancies including PC, several neurotrophins and their downstream receptors in PC cells after atorvastatin treatment were tested by western blotting. As shown in *Figure 5*, 10 nM of atorvastatin treatment significantly decreased the expression of NGF, BDNF, and NT-3 as well as that of their downstream receptors Trk A and Trk C but not that of Trk B. These results above indicated that atorvastatin may exert the anti-tumor effect in PC via the inhibition of neurotrophin signaling pathway.

Discussion

The results of the current study showed that atorvastatin, a cholesterol-lowering agent of the statin family, could be a potential anti-PC agent. Our data demonstrated that atorvastatin inhibited the proliferation of PC cells, as evidenced by the decreased viability and colony formation ability, induction of apoptosis and G1 phase cell cycle arrest. Furthermore, our results showed that atorvastatin activated p21 expression and reduced phosphorylation of Chk2-T68. We also found that atorvastatin treatment inhibited the migration and invasive capacity of PC cells. We further showed that atorvastatin treatment blocked neurotrophin signaling in two PC cells.

PC is one of the most aggressive human malignancies, with an extremely rapid proliferation ability and a high distant metastasis rate; it is resistant to conventional therapies, including chemotherapy and radiotherapy, and has a dismal survival rate of 6 months. To improve the outlook of this disease, additional novel therapeutic strategies are urgently needed. Some studies have assessed the antitumor effects of the statin family of drugs in several human malignancies, including breast, colon and ovarian cancers. However, the effect of statins on PC has not yet been fully studied. Guillaumond *et al.* (9) demonstrated that low-density lipoprotein receptor (LDLR), which facilitates cholesterol uptake, was associated with an increased risk of pancreatic ductal adenocarcinoma (PDAC) recurrence. Blocking LDLR reduced the proliferation potential of

Figure 2 Atorvastatin induces apoptosis in pancreatic cancer cells. PANC-1 and SW1990 cells were treated with different concentrations of atorvastatin for indicated times, and cell apoptotic rate was detected by flow cytometry (A and B). Statistical significance was presented as *, $P \leq 0.05$; **, $P \leq 0.01$.

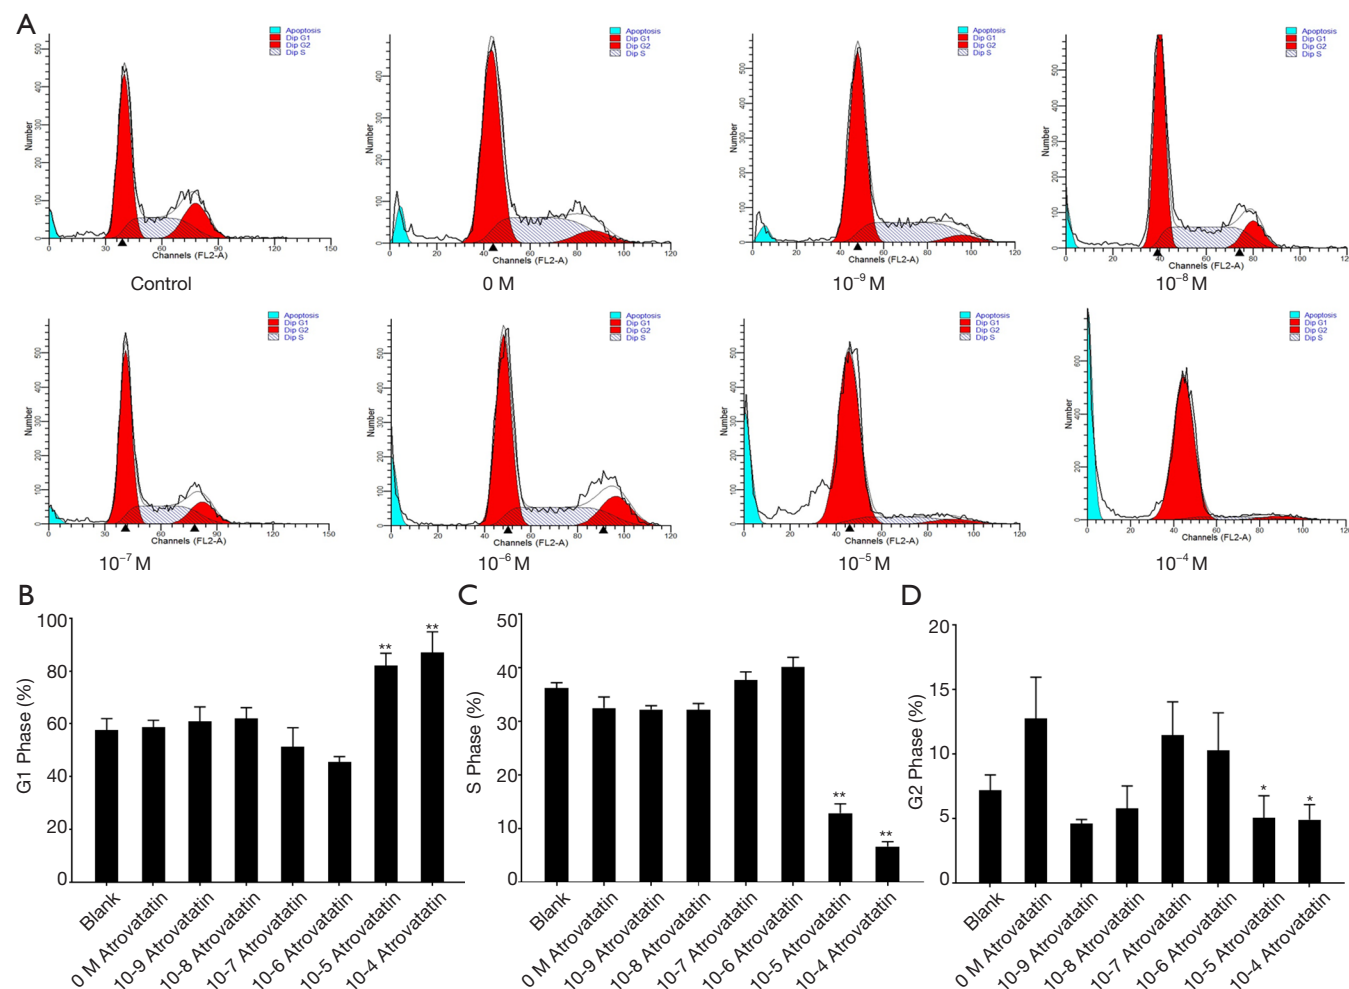

Figure 3 Atorvastatin induces G1-cell cycle arrest in PANC-1 cells. PANC-1 cells were treated with different concentrations of atorvastatin, and cell cycle distribution was detected by flow cytometry (A,B,C,D). Statistical significance was presented as *, $P \leq 0.05$; **, $P \leq 0.01$.

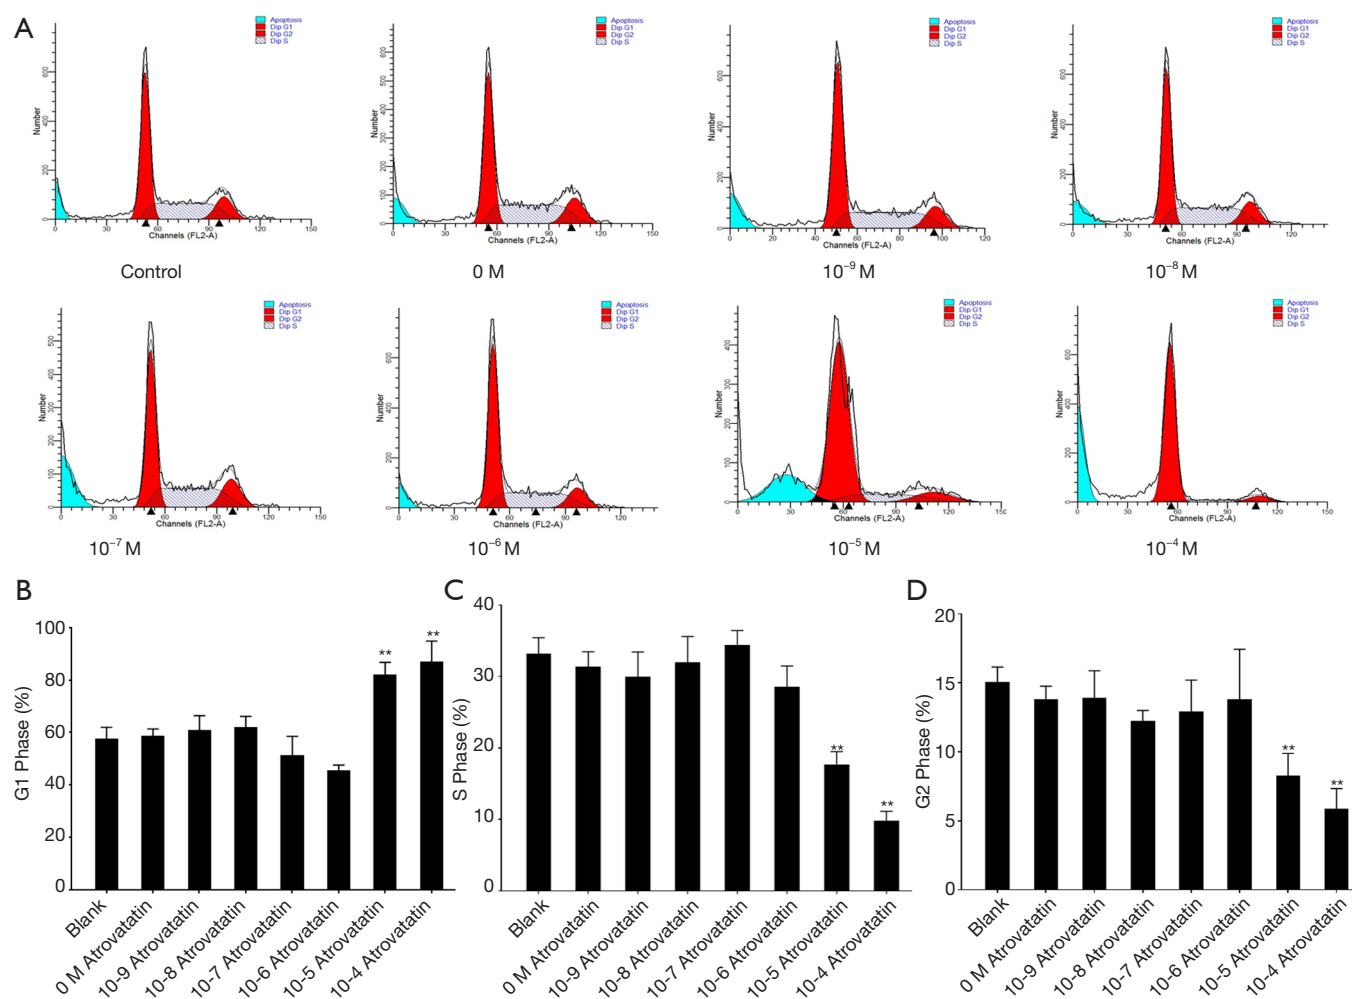

Figure 4 Atorvastatin induces G1-cell cycle arrest in SW1990 cells. SW1990 cells were treated with different concentrations of atorvastatin, and cell cycle distribution was detected by flow cytometry (A,B,C,D). Statistical significance was presented as **, $P \leq 0.01$.

PDAC cells. LDLR silencing sensitizes PDAC cells to chemotherapeutic drugs. In human PDAC, enhanced LDLR expression is associated with poor patient prognosis (9). Therefore, the use of an agent in the statin family to disrupt cholesterol uptake independently or in combination with chemotherapy may be a promising therapeutic strategy for these patients. In this study, the antitumor properties of atorvastatin were assessed by the cell viability assay, colony formation assay, flow cytometry, wound healing assay and Transwell invasion assay. The cell viability assay showed that at concentrations higher than 10 nM, atorvastatin treatment significantly inhibited the viability of PC cells in a dose-dependent manner. In the colony formation assay, atorvastatin treatment effectively inhibited the growth of PC cells. Flow cytometry data indicated that high-

dose atorvastatin treatment (10 nM or higher) induced apoptosis and G1-phase arrest in PC cells; both apoptosis and cell cycle arrest are currently topics of keen interest in cancer research. Furthermore, the wound healing assay and Transwell invasion assay showed that atorvastatin treatment (10 nM or higher) significantly inhibited the migration and invasion ability of PC cells. Taken together, we have shown that atorvastatin does exert anti-tumor effect in PC.

Neurotrophin signaling contains the upstream neurotrophins and their downstream receptors. The former is a family of structurally conserved growth factors, including NGF, BDNF, NT-3 and NT-4/5, while the latter includes TrkA, TrkB and TrkC. Increasing evidence suggests that dysregulated neurotrophin signaling plays a pivotal role in the development of cancer, including PC (14,15). A recently

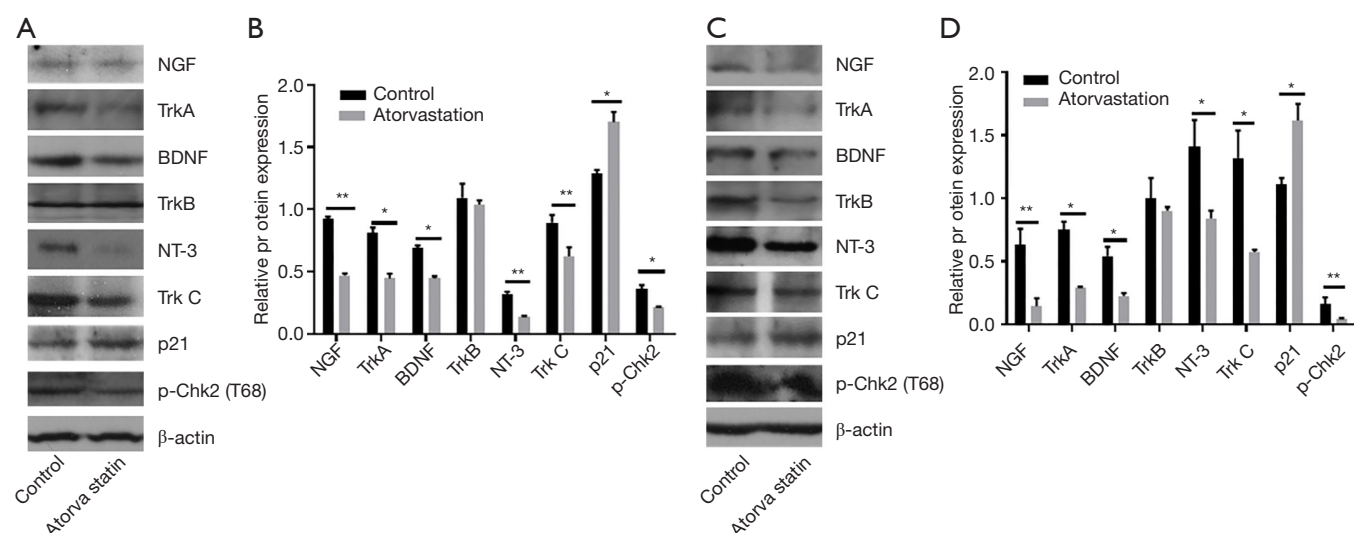

Figure 5 Mechanism underlying the antitumor effect of atorvastatin on pancreatic cancer cells. PANC-1 (A,B) and SW1990 (C,D) cells were treated with different concentrations of atorvastatin. Then, proteins were extracted and western blotting was performed for neurotrophin signaling proteins, p21, and β -actin was used as the loading control. Statistical significance was presented as *, $P \leq 0.05$; **, $P \leq 0.01$.

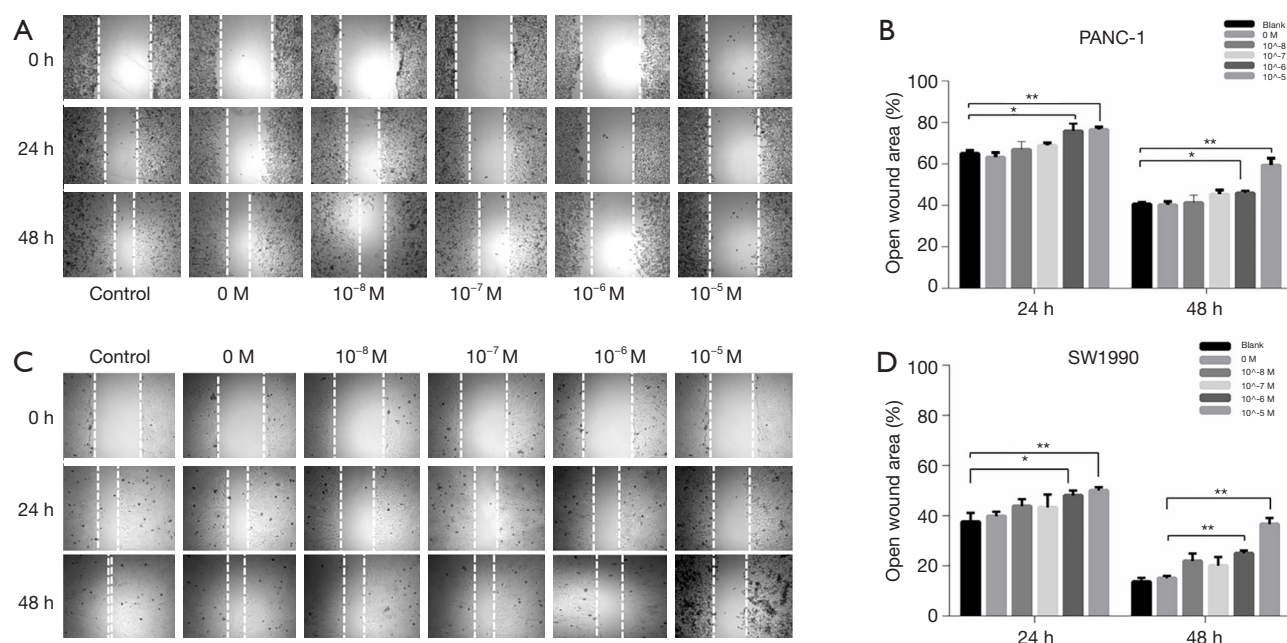

Figure 6 Atorvastatin inhibits migration in pancreatic cancer cells. PANC-1 (A,B) and SW1990 (C,D) cells were treated with different concentrations of atorvastatin. Then, wound healing assay was performed (A and C). Statistical significance was presented as *, $P \leq 0.05$; **, $P \leq 0.01$.

published *Cancer Cell* study found that NGF is overexpressed and promotes accelerated tumor development in PDAC cells, and therapy with a Trk inhibitor in conjunction with gemcitabine increased survival in a PC mouse model (16). Meanwhile, several clinical studies have indicated that

NGF, TrkA, TrkB, TrkC and other neurotrophin signaling members are aberrantly overexpressed in PC samples compared to that in normal adjacent tissues (17-19). Thus, neurotrophin signaling is one of the most attractive therapeutic targets in PC. To our knowledge, our results

Figure 7 Atorvastatin inhibits invasion. PANC-1 (A,B) and SW1990 (C,D) cells were treated with different concentrations of atorvastatin. Then, transwell invasion assay was conducted with crystal violet staining (A,C). The figures were shown with 10× magnification. Statistical significance was presented as *, $P \leq 0.05$; **, $P \leq 0.01$.

are the first to demonstrate that atorvastatin exerts anti-tumor effects and inhibits neurotrophin signaling in PC, as evidenced by the decreased NGF, NT-3, Trk A and Trk C levels after atorvastatin treatment. However, assessing the dependency of the atorvastatin-mediated antitumor effect on the inhibition of neurotrophin signaling is necessary.

Conclusions

The association between statin use and the prognosis of cancer patients is complicated. However, this study demonstrated that atorvastatin alone inhibited the proliferation, migration and invasion of PC cells by suppressing neurotrophin signaling. Thus, atorvastatin, an inexpensive, widely used lipid-lowering agent with a well-established safety profile, may be a potential anti PC agent. The antitumor effects of atorvastatin and the precise mechanisms underlying these effects will need to be further investigated *in vivo* in the future.
